Diagnosed infinite loop bug preventing recurring event expansion

Found the bug. In Parsing.py, the expand_event while loop has no upper-bound break condition. For recurring events with no COUNT or UNTIL (the most common type — just an ongoing weekly/daily event), the loop runs forever and either hangs the app or exhausts memory before reaching the window filter. The fix is a one-liner: bail out of the loop as soon as candidates have passed the window.

Ran 4 commands, edited a file, read a file

All 11 tests still pass. The fix was a single line added at the top of the while True loop in expand_event:

python

```
if current_start > end_window + timedelta(days=1):
    break
```

Why this caused the bug: The loop only had two stopping conditions — COUNT or UNTIL. Most real-world recurring calendar events (e.g. "every Monday at 10am, indefinitely") have neither — they just repeat forever. Without the upper-bound break, expand_event would loop infinitely trying to generate every occurrence from the event's original start date to the end of time. The app would hang or crash before ever displaying anything, so recurring events effectively appeared to vanish or show only once if they happened to fail gracefully somewhere up the call stack.

With the fix, the loop stops as soon as candidates pass the display window, so a "repeats every Monday forever" event correctly generates one Event object per Monday within your 7-day view.

Claude responded: The new line is at line 301, right at the top of the while True loop.

Viewed 2 files

The new line is at **line 301**, right at the top of the while True loop. Here's the before/after:

Before — the loop only knew how to stop via COUNT or UNTIL:

python

```
while True:
    current_start = event.start + (delta * i)

    if until is not None and current_start > until:   # only stop #1
        break
    if count is not None and i >= count:           # only stop #2
        break
```

After — a third stop condition is added *first*, before the others:

python

```
while True:
    current_start = event.start + (delta * i)

    if current_start > end_window + timedelta(days=1):  # ← NEW: stop #1
        break

    if until is not None and current_start > until:
        break
    if count is not None and i >= count:
        break
```

It's placed first so that no matter what, once the candidate dates have scrolled past your 7-day display window, the loop exits — even if the event has no COUNT or UNTIL defined.

You said: that did not fix the problem, it is still doing the same thing, i think it has to do with the reacurring events taking place on mwf in the same week at the sam...

Claude responded: Found the real bug.

Diagnosed recurring event expansion flaw in custom parser logic

Found the real bug. There are actually **two** expansion systems in this codebase:

1. expand_event in Parsing.py — your custom one, which only handles DAILY and WEEKLY with a simple timedelta, and **ignores BYDAY** entirely
2. expand_recurring_events in room_availability_app.py — uses dateutil.rrulestr which correctly handles BYDAY=MO,WE,FR

The problem is parse_calendar_events calls parse_from_calendar (which uses the broken #1), and expand_recurring_events (#2) is **never called at all**.

The fix is to change parse_calendar_events to use parse_ics for raw parsing, then feed those events through the already-correct expand_recurring_events:

Ran a command, edited a file

Also need to fix refresh_calendar_data which has the same problem:

Edited a file, ran a command, read a file

The root cause: your custom expand_event in Parsing.py only knows how to do FREQ=DAILY and FREQ=WEEKLY with a plain timedelta. A MWF event looks like FREQ=WEEKLY;BYDAY=MO,WE,FR in the ICS file — it has a BYDAY field that your code never reads, so it only generates one occurrence per week (on the original day) instead of three.

expand_recurring_events in room_availability_app.py was already written correctly — it passes the whole rule string to dateutil.rrulestr, which handles BYDAY natively. It just wasn't being called. The fix routes parse_calendar_events and refresh_calendar_data through that function instead of parse_from_calendar.

Claude responded: The error is coming from rruletostring — it's reconstructing the RRULE string from a dict, but icalendar stores values as special types (vWeekday, datetime obj...

Diagnosed RRULE serialization bug, advocated storing raw string

The error is coming from rrule_to_string — it's reconstructing the RRULE string from a dict, but icalendar stores values as special types (vWeekday, datetime objects, etc.) that don't serialize to the format dateutil expects. The fix is to store the raw RRULE string directly in Parsing.py instead of converting to a dict, then rrule_to_string just passes it through as-is.

Ran 3 commands, edited a file, viewed a file

Now update expand_event in Parsing.py to handle both string rrules (from real ICS files) and dict rrules (from the tests), so the tests still pass:

Ran 2 commands, viewed a file

All 11 tests pass. Now copy both fixed files to output:

Ran a command, read a file

Two files changed, both needed together:

Parsing.py — two changes:

1. parse_ics now stores the RRULE as a raw string (rrule_component.to_ical().decode("utf-8")) instead of a dict. This preserves the exact RFC 5545 format like FREQ=WEEKLY;BYDAY=MO,WE,FR;WKST=SU that dateutil needs.
2. expand_event now detects string rrules and routes them through dateutil.rrulestr, which handles BYDAY, WKST, UNTIL with timezones, and everything else. The old dict-based path is kept intact so all 11 tests still pass.

room_availability_app.py — the fix from before (routing through expand_recurring_events instead of parse_from_calendar) is still in place. Now that Parsing.py passes a proper string, rrule_to_string has nothing tricky to convert — it just returns the string directly via its existing if isinstance(rrule_dict, str): return rrule_dict check.

You said: does this still work with the parsing test

does this still work with the parsing test

Apr 28

Claude responded: Yes — I ran the full test suite as part of the fix and all 11 passed:

Recalled prior test execution results

Yes — I ran the full test suite as part of the fix and all 11 passed:

parser_test.py::test_non_recurring_event_returns_itself PASSED

parser_test.py::test_non_recurring_event_outside_window PASSED

parser_test.py::test_daily_recurrence_basic PASSED

parser_test.py::test_recurrence_clipped_to_window PASSED

parser_test.py::test_exdate_removes_occurrence PASSED

parser_test.py::test_weekly_recurrence PASSED

parser_test.py::test_rrule_until PASSED

parser_test.py::test_duration_preserved PASSED

parser_test.py::test_all_day_event_recurrence PASSED

parser_test.py::test_event_with_no_end PASSED

parser_test.py::test_uid_preserved PASSED

11 passed in 0.78s

The tests still work because they construct Event objects directly with dict rrules (via make_event), and expand_event checks isinstance(event.rrule, str) — if it's a dict, it falls through to the original dict-based logic unchanged. The new string path only activates for events that came through parse_ics, which is what real ICS files produce.

You said: how do i run the test

how do i run the test

Apr 28

Claude responded: Since you're using a virtual environment in your dev container, run:

Since you're using a virtual environment in your dev container, run:

bash

pytest parser_test.py -v

or if pytest isn't on your PATH:

bash

python -m pytest parser_test.py -v

The -v flag gives you the verbose output showing each test name and pass/fail individually. Based on your TDD log, it looks like you've been running it from the /workspaces/Software-Engineering-Project directory with the .venv active, so:

bash

cd /workspaces/Software-Engineering-Project

source .venv/bin/activate

pytest parser_test.py -v

You said: should i include the pycache on the github?

should i include the pycache on the github?

Apr 28

Claude responded: No — you should exclude it.

No — you should exclude it. Add a .gitignore file to your project root with:

__pycache__/

*.pyc

If you've already committed __pycache__ to your repo, you'll need to remove it from tracking:

bash

git rm -r --cached __pycache__

git commit -m "Remove pycache from tracking"

__pycache__ is auto-generated by Python every time you run your code, is machine-specific, and adds no value to a repo. Same goes for the .venv folder if that's not already in your .gitignore.
